

CSE 341 – PROGRAMMING LANGUAGES

Homework 2

Name – Surname: Muaz Kurt

Number: 151044062

Q1. Why can machine languages not be used to define statements in operational semantics?

A. The Operational semantics, are definition of a program state's effects on a machine. If the machine language is using for it, then a human can't learn language easily or read and understand a parse of a code in that language.

Q2. Write an attribute grammar whose BNF basis is that of Example 3.6 in Section 3.4.5 but whose language rules are as follows: Data types cannot be mixed in expressions, but assignment statements need not have the same types on both sides of the assignment operator.

A.

1. Syntax rule: $\langle \text{assign} \rangle \rightarrow \langle \text{var} \rangle = \langle \text{expr} \rangle$

Semantic rule: $\langle \text{var} \rangle.\text{actual_type} \leftarrow \langle \text{expr} \rangle.\text{actual_type}$

2. Syntax rule: $\langle \text{expr} \rangle \rightarrow \langle \text{var} \rangle[2] + \langle \text{var} \rangle[3]$

Semantic rule: $\langle \text{expr} \rangle.\text{actual_type} \leftarrow$

if (look-up($\langle \text{var} \rangle[2]$).string) = int) and (look-up($\langle \text{var} \rangle[3]$).string) = int) then int

else

if(look-up($\langle \text{var} \rangle[2]$).string) = real) and (look-up($\langle \text{var} \rangle[3]$).string) = real) then real

end if

end if

3. Syntax rule: $\langle \text{expr} \rangle \rightarrow \langle \text{var} \rangle$

Semantic rule: $\langle \text{expr} \rangle.\text{actual_type} \leftarrow \text{look-up}(\langle \text{var} \rangle.\text{string})$

4. Syntax rule: $\langle \text{var} \rangle \rightarrow A \mid B \mid C$

Q3. What are the reasons why using BNF is advantageous over using an informal syntax description?

A. Because;

it's easier to describe and understand rules from human and a machine with BNF than informal syntax analysis.

BNF based implementations can be easily maintain because of modularity of it. For example: Q2 and A2. If somebody try to maintain a part of the informal syntax description-based implementation, it's too hard because, he/she has to maintain all parts of it.

BNF descriptions can be used as the direct basis of a syntax analyser. Because it's all formal and just cares about what symbol is written and is it legal or not.

Q4. Describe briefly the three approaches to building a lexical analyser.

A. There are three approaches for building a Lexical Analyzer.

First: Write a formal description of the language using its regular expressions. So that we can easily create a lexical analyser with a common tool such: yacc, lex etc.

Second: Designing a state transition diagram (as a directed graph) that describes the tokens. Each node is a state and all edges are regular expressions that check the next character. This is a final state automata. If a node has not a matching edge (regular expression) for the next character, then there is an error. This is an automated lexical analyser.

Third: Design a state transition diagram as a table. This table describes the token patterns of the language. Then match the all lexemes with the tokens in the table by hand.
